AKARI data guide for beginners version 1.1 ~ DESCRIPTION OF THE AKARI DATA PRODUCTS ~

SUGAWARA Yasuharu^{*1}, MATSUZAKI Keiichi^{*1}, INADA Kuriko^{*1}, YAMAMURA Issei^{*1}

ABSTRACT

This document aims to introduce the archival data (mainly highly processed data such as catalogue, images, and spectra) taken by the AKARI infrared astronomy satellite, primarily for professional astronomers who are not necessarily familiar with AKARI. AKARI was launched on February 22, 2006, carried out numerous pointing observations as well as all sky surveys, and completed all the operations on November 24, 2011.

Keywords: Astronomy, Infrared, AKARI, data products

概要

本ドキュメントは、2006年2月22日に打ち上げられ、全天サーベイおよび、多数の指向観測を実施し、 2011年11月24日にすべての運用を終了した赤外線天文衛星「あかり」のアーカイブデータ(高次処理 データ:カタログ、イメージ、スペクトル)を天文学の研究者に紹介することを目的としています。

1. Summary of AKARI

Table 1 gives an overview of the "AKARI" satellite. Figure 1 shows the observation modes, wavelength-range and wavelength-resolution of two focal-plane instruments.

Launch date	e 1: Overview of the AKARI satellite.				
	February 22, 2006 (JST) May 2006 - August 2007 (Phase1&2: refrigerator + liquid helium cooling)

2. AKARI data products

Below, we introduce AKARI data products (=high-order processing data such as catalogue, images, spectra) created by the AKARI data processing and analysis team.

The AKARI data product is primarily classified according to the nature of the products: raw data (FITS format) or highlevel data products (catalogue, images, spectra). Next, they are separated by the detectors used, FIS⁴) or IRC⁶. Furthermore, they are divided into three attitude modes (All-sky survey mode, Staring mode, or Slow scan mode)¹. Figure 2 gives such a classification of the AKARI data products.

The AKARI position determination accuracy of a celestial object is within 5-6 arcsec. Table 2 gives explanation of all the data products, summarizing information on the official name of each product, the number of registered celestial bodies and detection sensitivity, etc.

The point source catalogue, all-sky images and spectra shown in Fig. 2 and Table 2 were first published on the homepage of the AKARI project team^{N2}) at ISAS/JAXA. They are permanently archived at DARTS^{N3}), which is the science data archive of ISAS/JAXA.^{N4})

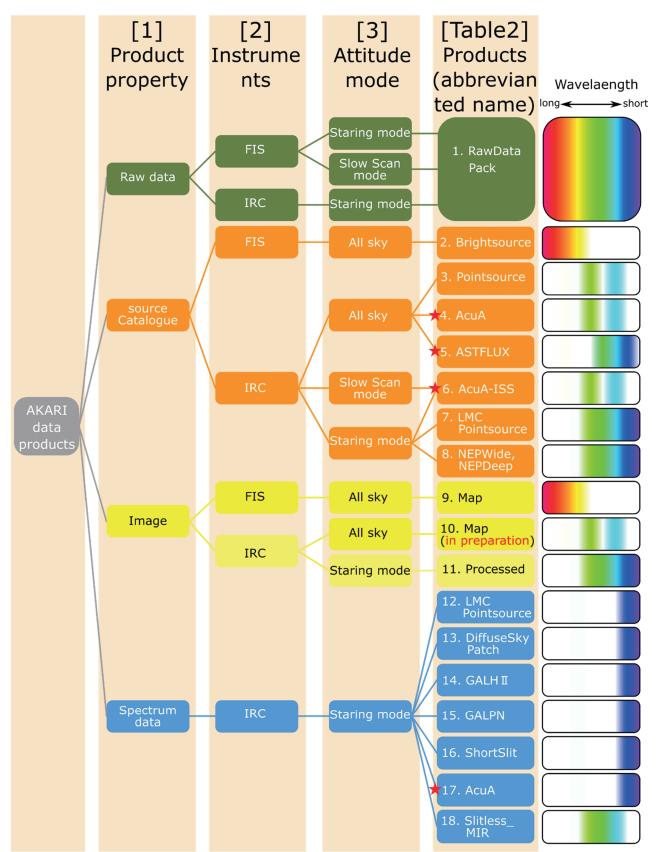

Figure 2: Classification of the AKARI data products. Raw data, catalogs, images and spectra are indicated in orange, yellow, and blue, respectively. The red stars represent products of the asteroids. The right-end column represents approximate wavelength range of each product. See Table 2 for explanation of each data product.

3. data product classification

3.1. Product property

The AKARI data products are divided into the following 4 categories.

(1) Raw data

Binary Table or Image FITS data.

(2) Source catalogue

Infrared source catalogue. There are all-sky catalogue, local region catalogue (LMC and NEP), and catalogue for asteroids.

(3) Images

FITS format image files. According to observation modes, they are classified into map images (All sky survey mode), pointing images (Staring mode), scan images (Slow scan mode).

(4) Spectra

Spectral data for various objects or fields.

3.2. Focal-Plane Instruments

At AKARI's telescope focal plane, two instruments, FIS⁴) and IRC⁵) were installed (Figure 3).

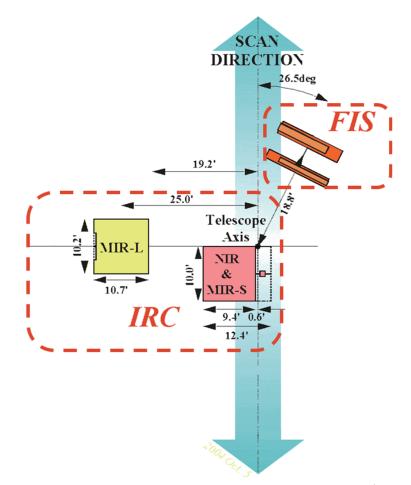

Figure 3: AKARI focal plane layout¹⁾. FIS is placed at the second focal point (see Figure 6), and IRC is placed at the first focal point (see Figure 7).

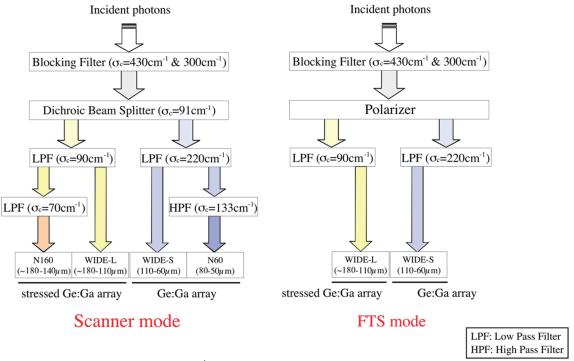

Figure 4: diagram of FIS optical path⁶⁾. Either left or right pattern of the optical path was possible.

3.2.1. FIS: Far-Infrared Surveyor

FIS was operational only when the liquid helium cooling was available, namely, from 7th May 2006 to 26th August 2007. It was mainly used for all-sky survey. As shown in Fig. 4, the light incident on the telescope passes through a beam splitter or interferometer (polarizer). Lights from different paths are collected by two different detectors. The optical paths and filters are different depending on the imaging and spectral modes. The following two modes were available:

(1) Scanner mode

Imaging observation was carried out with 4 band (wavelength band) of 65 (N60), 90 (WIDE - S), 140 (WIDE - L) and 160 (N160) μ m using different filters. Figure 5 shows the transmittance of each filter. In addition, as shown in Fig. 6, it was possible to capture 4 band images at once at two different fields of view. The scan direction was designed so that the same sky-area was scanned by the two fields of view successivly. This mode was usually used for all-sky survey observation, but also used for pointing observations.

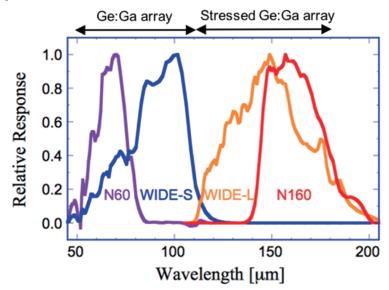

Figure 5: Transmittance of FIS filter⁴⁾.

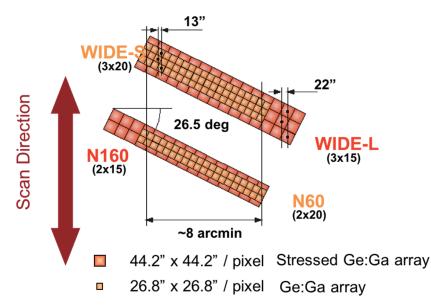

Figure 6: Fields of view of FIS projected on the celestial sphere⁴⁾. Detectors having overlapping fields of view are placed in different optical paths separated by the Dichroic Beam Splitter (see Figure 4).

(2) Fourier Transform Spectrometer mode (FTS mode)

By replacing the Dichroic Beam Splitter of Scanner mode with a Fourier spectrometer (polarizer), it is possible to perform spectroscopic observation using WIDE-S and WIDE-L detectors (Figure 4). Wavelength resolution varies depending on the optical path (scan time). FIS has "Full-resolution mode" and "SED mode", where Table 3 shows the spectral performance of each.

	orror manoo m	THE SPECTODES	
	detectors	wavelength	wavelength resolution $\lambda/\Delta\lambda$
		[µm]	
ſ	WIDE-S	60-110	150~450 (Full-resolution mode; scan time 48 sec)
	WIDE-L	110-180	or 23~75 (SED mode; scan time 12 sec)

Table 3: Performance in FIS spectroscopy mode⁶⁾.

3.2.2. IRC: InfraRed Camera

The IRC consists of three independent camera systems, NIR, MIR-S and MIR-L, which observe the wavelength bands of $1.7-5.5 \,\mu$ m, $5.8-14.1 \,\mu$ m, and $12.4-26.5 \,\mu$ m, respectively. IRC was used both for pointing observations and all sky survey.

Figure 7 shows the IRC fields of view. NIR and MIR-S cover the same field of view, where the same lights are split by the beam splitter for the two instruments. MIR-L has a different field of view and optical path. The fields of view of NIR/MIR-S and MIR-L do not overlap during scan.

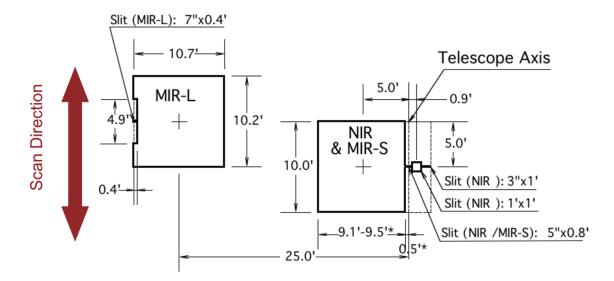

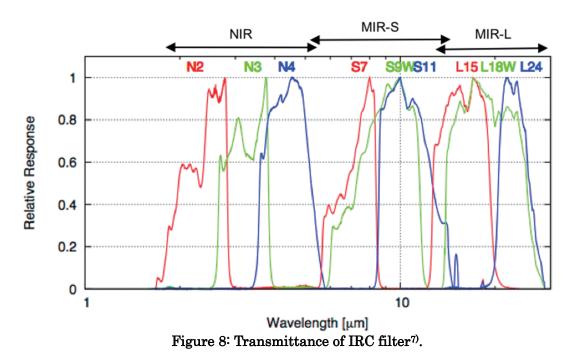

Figure 7: Fields of view and slit locations of the IRC⁵⁾.

(1) Imaging mode

Three kinds of imaging filters are mounted on each camera; NIR (N2, N3, N4), MIR-S (S7, S9W, S11), MIR-L (L15, L18W, L24). Figure 8 shows the transmittance of each filter.

(2) Spectroscopy mode

Each camera has two types of spectroscopic devices in addition to the imaging filters. Prism (NP) and grism (NG) can be selected in NIR by rotating the filter wheel. Either of two different types of grism can be selected for MIR-S (SG1, SG2), as well as for MIR-L (LG1, LG2). However, LG 1 of MIR - L was deteriorated in the ground test, so it was never used for observation. Table 4 shows spectral performance of each spectroscopic device.

Besides ordinary spectroscopic observation that introduces a point source in the slits (Figure 7), "slitless observation" which diffracts the entire imaging field of view was also carried out.

detectors	spectroscopic	wavelength [µm]	wavelength resolution
	device		[µm pix ⁻¹]
NIR	NP	1.8–5.2	$0.06 @ 3.5 \ \mu m^{N6)}$
	NG	2.5-5.0	0.0097
MIR-S	SG1	5.4-8.4	0.057
	SG2	7.5-12.9	0.099
MIR-L	LG1	(11-19)	(0.173)
	LG2	17.5-25.7	0.175

Table 4: Performance in IRC spectroscopy mode⁷⁾.

3.3. Attitude modes

AKARI conducted observations in the following three attitude modes. For details, please see Murakami et al. (2007)¹).

(1) All-sky survey mode

All-sky survey observation (3.6 arcmin/sec). In the end, more than 96% of the whole sky was covered.

(2) Staring mode

Pointing observation to observe specific sky-areas or objects with a fixed attitude. Pointing directions may be slightly shifted for dithering. Usually, staring mode spent up to about 10 minutes in an orbital period of about 100 minutes.

(3) Slow scan mode

Pointing observation to observe an extended region while slowly scanning (maximum 30 arcsec/sec). Sensitivity is several times higher than all-sky survey observation. As of October 2018, raw data of FIS and the asteroid catalog of IRC have been published for Slow scan mode.

4. Summary

AKARI was observed with two kinds of instruments, FIS and IRC. As of September 2019, two raw data sets, ten source catalogue, three-type images and seven spectrum sets have been published

REVISION HISTORY

Version 1.0 November 2018, First edition.

Version 1.1 September 2019, Correction of Figure 2 and Table 2.

-Introducing "product key".

-New spectral data added (AKARI Near Infrared Asteroid Spectral Catalog Ver.1 and AKARI/IRC MIR-S slit-less spectroscopic catalogue).

-Mistakes of instrument and wavelength of AKARI Asteroid Catalog fixed.

ACKNOWLEDGEMNETS

Advice and comments given by Prof. Ken Ebisawa and the AKARI data processing and analysis team members has been a great help.

Notes

- N1) Phase1: Observation period of the whole sky survey during the first half year.
 - Phase2: Observation period until the liquid helium is depleted.
 - Phase3: Observation period after the liquid helium depletion.
- N2) https://www.ir.isas.jaxa.jp/AKARI/Archive/
- N3) https://darts.isas.jaxa.jp/astro/akari/products.html.

N4) Observational information of the staring observations is published from DARTS. Users can investigate when and in which modes the targets were observed.

N5) For catalogs and images, the center wavelengths (see Figures 5 and 8) are indicated. For spectra, the wavelength ranges are shown (wavelength resolution is shown in Tables 3 and 4).

N6) The dispersive power of the NIR prism (NP) depends on the wavelength.
